

Agnostic post-processing changes masks

Example: plain attribution vs. max-pooling/Gaussian post-processing

DPI sanity check

$$I(Z; k(A) | X) \leq I(Z; A | X)$$

But ROAR/ROAD scores the modified input, so mask geometry can still improve the benchmark result.

Better removal score != more model information.

ROAR/ROAD can reward mask geometry, not model understanding

On Pitfalls of RemOve-And-Retrain: A Data Processing Inequality Perspective

Junhwa Song¹, Keumgang Cha², Junghoon Seo¹ · ¹PIT-IN Corp. · ²SI Analytics Co., Ltd.

1 TL;DR

MAIN 3 TAKEAWAYS

- Agnostic blur/max-pool cannot add model information.
- Yet it lowers ROAR/ROAD accuracy in most comparisons.
- ROAR/ROAD can reward low-TV mask geometry.

2 Background / Motivating Question

- ROAR removes high-attribution features and retrains; lower accuracy is interpreted as a better attribution.
- Low accuracy can arise from mask geometry, not from more information about the decision function.
- Can an agnostic k(A) improve scores without improving interpretability?

3 Theory: DPI sanity check

- For fixed X, agnostic post-processing forms $Z \rightarrow A \rightarrow k(A)$.
- DPI: $I(Z; k(A) | X) \leq I(Z; A | X)$, so k cannot add model-side information.
- Still, thresholding k(A) changes the mask and can lower $I(X^t; Y)$.

DPI says k(A) cannot add model-side information

Conditional Markov chain
 $Z \rightarrow A \rightarrow k(A)$ given X

Data processing inequality
 $I(Z; k(A) | X) \leq I(Z; A | X)$
Blur/max-pool cannot add model information.

Counterexample
k can destroy all Z-information yet make the thresholded mask remove more class-relevant input, lowering $I(X^t; Y)$.

4 Experiments: post-processing wins

DATA: CIFAR-10, SVHN, CUB-200
MODELS: ResNet18 / ResNet50
k(A): max-pool 3x3 or Gaussian sigma=1
MAPS: 9 maps x 3 drop rates
LOWER ACCURACY = better ROAR/ROAD score

Directional evidence

Post-processing lowered final accuracy

Blurriness bias

R^2 between total variation and ROAR accuracy

Dataset	t=10%	t=30%	t=50%
CIFAR-10	0.84	0.85	0.82
SVHN	0.92	0.90	0.95
CUB-200	0.91	0.90	0.92

Lower TV = blurrier masks

ROAR/ROAD often treats lower accuracy as better, so blur can be rewarded even when it is agnostic.

- Lower total variation (TV) means blurrier masks.
- TV predicts ROAR accuracy with $R^2 = 0.82-0.95$.
- GC^2 is less affected because its maps have lower resolution.
- Mask smoothness is a benchmark confound.

5 Discussion

- Do not rank attribution methods solely by ROAR or ROAD.
- Report mask TV, mask visuals, ablations, and sanity checks with removal scores.
- Image results may not transfer unchanged to text, graph, or time-series settings.
- Prefer evaluations that directly target decision-function information.
